

CPAP HUMIDIFIER

CROSS-REFERENCE TO RELATED APPLICATION

This application claims the benefit of U.S. Provisional Patent Application Serial No. 60/225,171 filed on August 14, 2000.

BACKGROUND OF THE INVENTION

Field of the Invention

The present invention relates generally to a passive humidification apparatus, and more specifically to a humidifier for a continuous positive airway pressure (CPAP) device.

Relevant Prior Art

CPAP devices are now commonly used to treat a variety of respiratory disorders, including sleep apnea. CPAP devices normally consist of an air pump connected to a mask worn by a patient while they are sleeping.

Although CPAP devices have been very successful in treating these disorders, there is at least one associated drawback. The air that is introduced into the patient's respiratory system tends to have the effect of drying out mucous membranes. In order to mitigate this problem, several types of passive humidifiers have been developed that can be connected between the CPAP device and the associated mask without interfering with the normal operation of the device.

00000000.001501

1 One such passive humidifier is disclosed in U.S.
2 Patent No. 5,231,979 to Rose et al. This humidifier
3 consists mainly of a chamber having an inlet and an
4 outlet and that is partially filled with water. In
5 operation, the outlet of a CPAP device is connected to
6 the inlet of the humidifier and the mask is connected to
7 the outlet of the humidifier. When the air supplied by
8 the CPAP device enters the humidifier chamber and passes
9 over and contacts the water, some moisture is added to
10 the air through evaporation before the air ultimately
11 passes to the mask and into the patient. This
12 humidifier, however, is very ineffective and normally
13 produces insufficient levels of humidity.

14 To improve the efficacy of the passive
15 humidification system, some such humidifiers have been
16 provided with baffles located within the humidifier
17 chamber. One such baffled humidifier is disclosed in
18 U.S. Patent No. 5,598,837 to Sirianne, Jr. et al. In
19 this humidifier, air is made to flow around the baffles
20 which increases its length of contact with the water and
21 also tends to augment the evaporation process. However,
22 this humidifier design still falls short of providing an
23 optimum level of moisture in the output air.
24 Additionally, the shape of this humidifier precludes most
25 CPAP devices from resting on top of the humidifier, and
26 thus it significantly increases the footprint of the CPAP

1 system.

2 BRIEF SUMMARY OF THE INVENTION

3 According to one aspect of the present invention, a
4 humidifier for a continuous positive airway pressure
5 device is provided. The humidifier comprises a
6 humidifier body, an air inlet provided to the humidifier
7 body, an air outlet provided to the humidifier body, and
8 a plurality of chambers defined within the humidifier
9 body. The humidifier further comprises a plurality of
10 baffles between one of the plurality of chambers and an
11 adjacent one of the plurality of chambers, an opening
12 provided between two of the plurality of baffles, the
13 opening connecting the adjacent two of said plurality of
14 chambers, and a deflector baffle being one of the
15 plurality of baffles, the deflector baffle being located
16 proximate to the opening and defining a serpentine fluid
17 flow path between the adjacent chambers.

18 According to another aspect of the present
19 invention, a humidifier comprises a non-planar dividing
20 wall separating an adjacent two of said plurality of
21 chambers, and an opening in the dividing wall providing
22 fluid communication between chambers.

23 According to a further aspect of the present
24 invention, a humidifier comprises a base, a cover having
25 a resilient peripheral portion removably securing the

1 cover to the base, a chamber defined by the base and
2 cover, an inlet in communication with the chamber, and an
3 outlet in communication with the chamber.

4 BRIEF DESCRIPTION OF THE DRAWINGS

5 FIG. 1 is perspective view of a CPAP humidifier
6 according to an embodiment the present invention;

7 FIG. 2 is plan view of the CPAP humidifier of FIG.
8 1;

9 FIG. 3 is a plan view of a cover portion of the CPAP
10 humidifier of FIG. 1;

11 FIG. 4 is a perspective view of the cover portion of
12 FIG. 3;

13 FIG. 5 is a detail of air flow within a CPAP
14 humidifier according to an embodiment of present
15 invention;

16 FIG. 6 is a sectional view taken along section line
17 6-6 of the CPAP humidifier shown in FIG. 2;

18 FIG. 7 is a sectional detail showing a seam of the
19 CPAP humidifier of FIG. 6;

20 FIG. 8 is a perspective view of a CPAP humidifier
21 according to another embodiment of the present invention;
22 and

23 FIG. 9 is a sectional detail taken along section
24 line 9-9 of the CPAP humidifier shown in FIG. 8.

DETAILED DESCRIPTION

In a passive humidification system, factors contributing to humidification include increased surface contact and decreased air pressure. By controlling these factors through humidifier design, the overall performance of the humidifier can be increased.

One way to positively affect both of these factors is by preventing laminar air flow through the system. When turbulence is introduced, the air does not travel in a straight line, and thus it will remain in the system longer and have increased surface contact with the water. Furthermore, assuming a constant input and output pressure, turbulent flow has the effect of increasing airflow velocity within the system. When the velocity of the air flowing across the surface of the water is increased, the air pressure above the water correspondingly decreases which effectively increases the rate of evaporation. Turbulent airflow can be created in several ways.

One way to create turbulence in a system is by designing the system with a high Reynolds number. As will be appreciated by one skilled in the art, the higher the Reynolds number, the greater the incidence of turbulent flow. The Reynolds number of a system is directly related to the velocity of flow. In the present humidifier design, positive pressure is placed on the air

00000000-00000000

1 inlet, thereby increasing the velocity of the air
2 traveling through it.

3 Another way to increase turbulence and air velocity
4 is by providing baffles that redirect the airflow.
5 Further, by constricting the airflow space, the baffles
6 will tend to increase the Reynolds number of the system.

7 As will be shown below, the shape and placement of
8 baffles in the system are critical to providing the
9 desired effect.

10 FIGS. 1 and 2 show the exterior of a CPAP humidifier
11 10 according to the present invention. The humidifier 10
12 is provided with an air inlet 12, an air outlet 14, and a
13 humidifier chamber 16. In use, the inlet 12 is connected
14 to the outlet of a CPAP device (not shown) and the outlet
15 14 is connected to a patient delivery device, such as a
16 mask (not shown). Both of these connections are normally
17 accomplished using flexible hose. As best seen in FIG.
18 1, the humidifier 10 comprises a cover portion 18 and a
19 base portion 20.

20 FIGS. 3-5 show the cover 18 of the humidifier 10
21 removed from the base 20. The cover 18 is provided with
22 a plurality of arced baffles 22. Alternatively, the
23 baffles 22 could be curvilinear, flat or formed from a
24 plurality of flat portions connected at an angle.

25 The baffles 22 are arranged to form non-planar
26 dividing walls so that the humidifier chamber 16 is

effectively divided into four separate parallel chambers 24, 26, 28, 30. The term non-planar as used herein with reference to the dividing wall refers to a body that is made up of at least two separate components which are not coplanar with respect to one another. For example, the wall of the present embodiment comprises individual baffles 22 which are curved and/or angled with respect to one another.

The first chamber 24 is adjacent to the air inlet 12 and the second chamber 26. The second chamber 26 is also adjacent to the third chamber 28. The third chamber 28 is also adjacent to the fourth chamber 30. The fourth chamber is also adjacent to the air outlet 14.

Openings 32 are provided between adjacent baffles 22 to allow adjacent chambers 24-30 to communicate with one another. Further, the baffles 22 do not extend completely to the base 20, leaving a space connecting all of the chambers 24-30. Each of the openings 32, excluding one opening 34 that is in closest proximity to the air outlet 14, is provided with a deflector baffle 36 spaced away from the opening 32. The deflector baffle 36 is provided as part of the dividing wall and defines a serpentine flow path between two adjacent chambers. The term serpentine, as used herein, refers to a path which is not linear, having at least one bend. As an alternative, a deflector baffle could be provided at

1 deflection and the inertia of the air molecules, the air
2 is distributed along the length of the first chamber 24.
3 Continued airflow from the inlet 12 forces the air toward
4 the first set of baffles 22 and eventually through the
5 openings 32.

6 The deflectors 36 create back-pressure and prevent
7 the air from passing to the second chamber 26 too
8 quickly. The deflectors 36 also direct the air outward
9 from the openings 32 and around the arced baffles 22.
10 This air movement continues through the second chamber 26
11 and third chamber 28 until the air is finally pushed into
12 the fourth chamber 30 and through the outlet 14.

13 As shown in FIG. 5, during the time when the air is
14 with each chamber 24-30, a cooperation between the arced
15 shape of the baffles 22, the position of the openings 32
16 and the deflection of the deflectors 36 causes the
17 airflow to enter in an indirect serpentine fashion and
18 circle a number of times within each chamber 24-30 before
19 it exits through the opening 32. The indirect airflow
20 and circling or eddying 44 causes additional turbulence,
21 resulting in increased airflow velocity and significantly
22 extending the duration of contact between the air and
23 water. All of these effects taken together lead to
24 enhanced evaporation and humidification of the air within
25 the chamber. The curved corners 46 of the chamber 16
26 have a radius that matches the baffles 22 to further

enhance the eddy effect.

Since the baffles 22 do not extend fully to the base 20, the water is free to flow within the chamber 16. This helps to further enhance evaporation and minimize the energy necessary to break water molecules away from the surface of the water by decreasing the effect of surface tension. Thus, as shown in FIG. 6, the direction of air flow tends to cause the water level in each successive chamber 24-30 to be higher than the previous one. For this reason, no deflector 36 is provided at opening 34, helping to prevent excess back-pressure from accumulating and causing water to be forced through the outlet 14.

Further, both the inlet 12 and the outlet 14 are raised above the top of the cover 18 to help prevent water from inadvertently flowing out of the chamber 16.

In addition to humidifier efficiency, the design of the humidifier 10 is based on some other considerations. The cover 18 is provided with lateral ribs 48 that provide help to stiffen the surface of the cover 18. This, along with the flat top design of the cover 18, allow a CPAP device to be placed on top of the humidifier to minimize the overall footprint. The ribs 48 have been strategically positioned to help trap airflow and to some degree enhance the eddying effect. Additional ribbing 50 is provided on the exterior surface of the base 20 to

1 provide additional strength. This ribbing 50 is designed
2 to mirror the baffles 22 within the chamber 16 for purely
3 aesthetic reasons.

4 As shown in FIGS. 1-2, the cover 18 can be
5 molded from a single piece of rigid plastic and
6 permanently secured to the base 20. As shown in FIG. 7,
7 the cover 18 is secured to the base 20 using a permanent
8 adhesive 52. Since many prior art devices are clamped
9 together and sealed with a flexible gasket, they are more
10 prone to leakage. To further prevent leakage, a tongue
11 54 provided on the cover 18 fits into a groove 56
12 provided on the base 20 and the adhesive 52 fills a void
13 58 between the tongue and the groove. Excess adhesive 52
14 flows into gaps 60 that remain between the cover 18 and
15 the base 20.

16 Alternatively, as shown in FIG. 8, a removable cover
17 18' can be used. The removable cover 18' is formed as
18 two-piece structure. A main cover portion 18a is formed
19 from rigid material, like that of the one-piece cover 18.
20 The main portion 18a is surrounded by a sealing cover
21 portion 18b that is formed from a flexible material, such
22 as rubber, molded around the main portion 18a. The
23 flexible sealing portion 18b forms a sufficiently air and
24 water tight seal with a modified base 20', but is
25 removable from the base 20' to allow the interior
26 surfaces of the humidifier 10 to be cleaned. The

1 departing from the fair scope of the teaching contained
2 in this disclosure. The invention is therefore not
3 limited to particular details of this disclosure except
4 to the extent that the following claims are necessarily
5 so limited.
